### 1. Density estimation

**Density estimation** is the unsupervised task of learning an estimator for the joint probability distribution  $p(\mathbf{X})$  from a set of i.i.d. samples  $\mathcal{D} = \{\mathbf{x}^i\}_{i=1}^m$  over RVs  $\mathbf{X} = \{X_1, \dots, X_n\}$ 

Given such an estimator, one uses it to answers probabilistic queries about configurations on X, i.e. to do *inference*.

The main challenge in density estimation is balancing:

- the *representation expressiveness* of a model
- ⊕ the *cost of learning* it
- and the cost of performing inference on it.

# 2. Tractable Probabilistic Models (TPMs)

Classical Probabilistic Graphical Models like *Bayesian Networks* (BNs) and *Markov Networks* (MNs) are highly expressive but exact inference is generally *NP-hard* [6].

Tractable Probabilistic Models (TPMs) on the other hand, are density estimators for which some kind of exact inference is tractable, i.e. polynomial in the number of RVs or their domains.

→ learning may still not scale to multidimensional data

**2.1 Product of Bernoullis (PoBs)** PoBs are the least expressive TPMs, assuming all RVs to be independent:

However, learning a PoBs is fast:  $\rightarrow$  linear complexity O(nm)

#### 2.2 Chow-Liu Trees (CLTrees)

A directed tree-structured model [3] over  $\mathbf{X}$  is a BN in which each node  $X_i \in \mathbf{X}$  has at most one parent,  $\mathrm{Pa}_{X_i}$ .

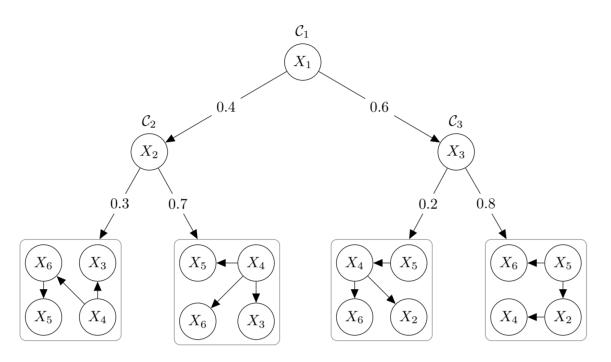

Learning a CLtree takes quadratic time  $O(n^2(m + \log n))$ 

### 3. Cutset Networks (CNets)

A Cutset Network (CNet)  $\mathcal C$  is TPM represented via a weighted probabilistic model tree over  $\mathbf X$  and recursively defined as:

- 1. a TPM  $\mathcal{M}$ , with  $\mathsf{scope}(\mathcal{M}) = \mathbf{X}$
- 2. a weighted disjunction (OR node) of two CNets  $\mathcal{C}_0$  and  $\mathcal{C}_1$  conditioned on RV  $X_i \in \mathbf{X}$ , with weights  $w_i^0$  and  $w_i^1$  s.t.  $w_i^0 + w_i^1 = 1$ , where  $\mathsf{scope}(\mathcal{C}_0) = \mathsf{scope}(\mathcal{C}_1) = \mathbf{X}_{\backslash i}$

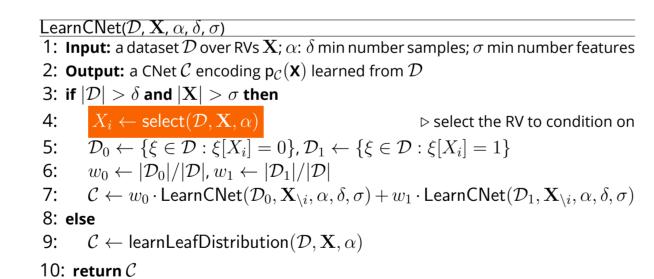

A CNet over binary RVs  $\mathbf{X} = \{X_1, \dots, X_6\}$ . Or nodes are rounded, while leaf squared nodes represent CLtrees.

Therefore, the joint pdf modeled by a CNet  ${\mathcal C}$  is:

 $p(\mathbf{x}) = p_l(\mathbf{x}_{|\mathsf{scope}(\mathcal{C}) \setminus \mathsf{scope}(\mathcal{M}_l)}) p_{\mathcal{M}_l}(\mathbf{x}_{|\mathsf{scope}(\mathcal{M}_l)}) \tag{1}$ 

## 4. Learning CNets

All top-down greedy CNet learners can be unified in single template, LearnCNet:

different select implementations have different complexities:

entCNet [5] choosing  $X_i$  to lower approximate average joint entropy  $\rightarrow O(mn^2)$ 

**dCSN** [2] choosing  $X_i$  in a principled way improving likelihood  $\rightarrow O(n^3(m + \log n))$

## 5. XCNets

**XCNets** (Extremely Randomized CNets) are CNets built by LearnCNet when select chooses one RV completely at random. select time complexity  $\rightarrow$  O(1)

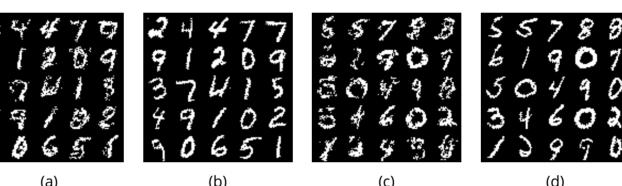

#### **5.1 Mixture of Experts Interpretation**

A single CNet can be seen as a peculiar *mixture of experts*: the OR tree plays as a *deterministic gating function* and leaf distributions as *local experts*.

A path  $p=p_{(1)}p_{(2)}\cdots p_{(k)}$  connects the root to a single leaf  $\mathcal{M}_l$  after observing  $x_1x_2\cdots x_k$ , Equation 1.

 $\mathsf{p}_l(\mathbf{x}_{|\mathsf{sc}(\mathcal{C})\setminus\mathsf{sc}(\mathcal{M}_l)})$  is decomposed by the chain rule across path p .  $\to$  shuffling  $X_{p(0)},\ldots,X_{p_k}$  does not influence inference!

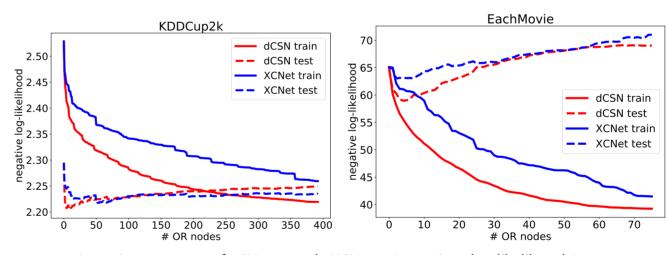

Therefore, a single XCNet is only only slightly less accurate than a CNet and as good at generating samples.

Samples obtained from a CNet (a), resp. XCNet (c), learned on a binarized version of MNIST, and their nearest neighbor in training set (b), resp. (d).

#### **5.2 Regularizing learning**

Single CNets learned with LearnCNet are prone to overfitting, randomization in XCNets alleviate this issue

Learning curves of CNets and XCNets (negative log-likelihoods) on KddCup2k and EachMovie. The latter overfits much later that the former.

**5.3 Ensembles** of XCNets do not require to additionally diversify components and learning up to 500 components is still faster than learning 40 of other variants:

 ${f CNet}_{bag}$  bagging entCSN models as in [4]  ${f CNet}_{boost}$  boosting entCSN models as in [4]  ${f dCSN}^k$  bagging dCSN models as in [2, 1]
